## What Gives?

Vanessa Ma | Shyamsunder Sriram

**BUSN 37304** 

### Context

## **Optimizing Philanthropy**

- Nature: not-for-profit organization
- Operations: provides programs and services for US veterans with spinal cord injuries or disease
- How they make money: direct mail fundraising with an in-house database of over 13 million donors

## **Goal: Increase Philanthropic Returns** for Direct Mailing Campaigns

- Maximize profit: increase the funds received from upcoming philanthropic campaigns, through 2 possible ways:
  - Increase recurring donor pool
  - Increase number of big ticket donors
- Lower costs: reduce number of 'failed' mailings, i.e. mailings to people who will not respond
- Possible particular group of interest: reining back lapsed donors
  - Defined as: donors who last gave 12-14 months ago
  - Believe that the longer a donor goes without giving, the more likely he / she will fall off the map

## **Objective**

## Can we increase returns by selective mail?

Predicting **WHO** Will Donate

2

Predicting HOW MUCH They Will Give

<sup>\*</sup>The presentation is structured according to the best practices shown in session 1 of this class, providing a 'recipe' for good algorithm-making:

## Theory & Model

## **Theory**

## **Two Utilities for Two Separate Decisions**

#### **Decision 1: To Donate Or Not?**

#### Similar to choice to buy or not to buy

- Functionally not different from committing to a "method" of spending money
- Binary decision, classification question
- Hypothesis: driven by connection to the organization (i.e. census, interest variables)

#### Utility theory applies:

- $U_1(X_i^1) = \alpha^1 + \beta^1 X_i^1 + \epsilon$
- X<sub>i</sub><sup>1</sup>: for individual i, a characteristic set (1) that helps them understand the utility gain from this decision (e.g. neighbourhood, connections)
- $\alpha^1$ : baseline utility value.
- committing to donating gives them more utility than not donating

#### **Decision 2: If I Donate, How Much?**

#### **Dissimilar** to purchasing!

- The donation is not fixed there is no price, customer freely decides
- Continuous variable, regression question
- Hypothesis: largely driven by ability to give (i.e. income, wealth)

#### Utility theory applies:

- $U_2(X_i^2) = \alpha^2 + \beta^2 D(X_i^2) + \epsilon$
- $X_i^2$ : for same individual i, different characteristic set
- *D*(...): function that outputs giving amount based on individual characteristics
- α<sup>2</sup>: baseline utility value, likely 0.
- donating to this organization gives them more utility than giving to any other

## **Theory**

## **Modelling the Two Utilities Separately**

#### **Logistic Regression**

- To Donate or Not is a binary variable
  - classification question
- Linear models would not make sense
- Chosen for simplicity

#### **Output: probability of donating**

$$P(W_i = 1) = \frac{1}{1 + e^{-(\alpha + \beta X_i)}}$$

- P(...): probability distribution of logit
- W<sub>i</sub>: individual i's choice to donate (1) or not to donate (0)
- $\alpha + \beta X_i$ : individual's utility regarding the choice to donate or not to donate

#### **Generalized Linear Regression**

- How Much to Donate is a continuous variable
- Conditional probability question, given that a person is classified with response = donate
- Linear regression model would work well
- Chosen for simplicity and lower requirements for computing power

#### **Output: expected donation value**

$$D(X_i) = mX_i + C$$

- D(...): function for donation value given individual i's parameters
- m : weights vector for predictive parameters

## Data

**Exploratory Data Analysis** 

### **Dataset Overview**

## Results a mailing that was dropped in June 1997 to a total of 3.5 million PVA donors

- included a gift "premium" of personalized name & address labels plus an assortment of 10 note cards and envelopes
- donors were acquired through similar mailings in the past.

#### **Types of Variables**

#### **Demographics**

- First record, frequency of giving
- Age, location, gender, income

#### **Mail Order Responses**

- Number of times donor has responded to other types of mailing offers
- · E.g. Craft hobbies, gardening, magazines

#### **Sources of Overlay Data**

- Solicitation limits, connection to PVA-related organizations e.g. Military, Government
- Third party data origin

#### **Interests**

- Donor interests collected from third-party sources (binary variables)
- E.g. stereo, pets, collectables

#### Census

- Characteristics of donor neighbourhood from 1990 Census
- E.g. race, education level, poverty level

#### **Promotions**

- Giving history for last 24 mailings
- Lifetime giving statistics: total amount, frequency, first gift, average gift etc

## **Propensity Scores**

#### **UPSHOT: MAILINGS ARE NOT RANDOMIZED EXPERIMENTS**

## **Propensity Scoring** to verify randomized nature of the data

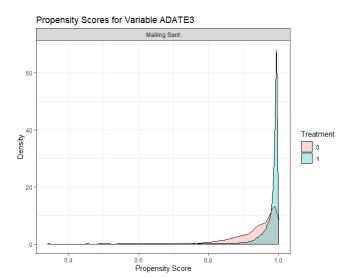

- Only conducted on 5 of 24 available mailings
  - ADATE3, ADATE7 examples shown on right
- Key assumption made: replicable mailing policy, such that results from one mailing can be cross-applied to all mailings)

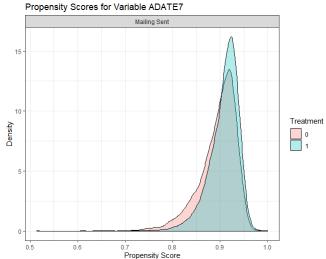

#### **Findings**

- skew heavily towards 1 (Should be at 0.5)
- indicating non-randomization / possible selection bias

#### Conclusion

- Current policy is a "blast mailing" policy
- · Mail to nearly all without discrimination

## Covariate (Im)Balance

#### **UPSHOT: THERE IS NO CONTROL GROUP**

## The "accidental" non-mailed minorities – can they be treated as a control?

 Due to sheer amount of covariates (>500), only 10 were analysed

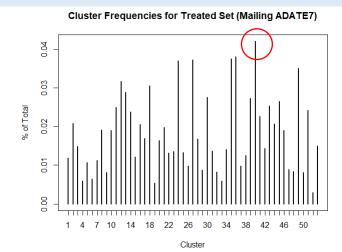

#### **Cluster** as example (right):

- Serves as needed **proxy** for weighted average of a few key variables:
- E.g. socioeconomic status, gender, geographical location, age
- Coded for and provided by PVA

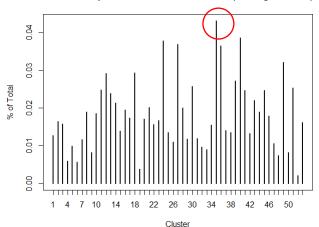

#### **Findings**

- Differing % make-up of Treated and Non-Treated Set – <u>at the least, different modes</u>
- Similarly non-comparable results found for other tested variables
  - Income, Homeowners, Wealth (Socioeconomic)
  - Domain, PVA State, Age (Demographics)
  - Veterans, Fisher, Collect1 (Logged Interests)

**Conclusion: No** 

#### Cluster Frequencies for Non-Treated Set (Mailing ADATE7)

## **Defining a Target Measure**

LIFT

=

**TARGET PROFITS** 

-

**BASELINE** 

#### **Target Profits**

#### Typically

- For every customer: Spend\* Cost
- Choose to target N<sup>^</sup> people out of population N, depending on targeting policy
- If Lift > 0, then the policy is good!

#### For us

- No meaningful difference, directly applicable for N<sup>^</sup> donors targeted (N<sup>^</sup> <= N)</li>
- Cost = \$0.68, flat rate for sending a promotion
- Spend\* = Donation = \$??
  - · Value determined by donor
  - \$0 if no response

Profits = SUM(Donations) - Cost \* N^

#### **Baseline**

#### Typically

- For each customer: Spend (without marketing)
- Assumes:
- there are other methods to acquire the same product / service / item
- Control group exists upon which to make these estimates

#### For us, **Key Assumptions Violated:**

- no other way of donating except for campaign
- no control group exists

Thus, baseline is status quo:

Profits if everyone (N) was mailed

Baseline = SUM(Donations) - Cost \* N

<sup>\*</sup> Spend\* refers to amount spent post marketing campaign. Presumably, spend\* > spend.

### **Final Profit Model**

#### **Model Goal**

- Let X be a random variable that represents whether a prospective donor donates.
  - X = 1 if the person is a donor
  - X = 0 if the person is NOT a donor.
- Let Y be a random variable that represents the value of the donation given.
- Let Z be the cost of mailing.
- We want to figure out the predicted donations for each donor of the joint distribution (X, Y).

#### **Model Approach**

- Calculate f<sub>1</sub>(X) from our logistic regression model.
- Calculate  $f_2(Y \mid X = 1)$  from our **linear regression** model.
  - In other words  $f_2(Y \mid X = 1)$  translates to: given a set of people willing to donate, how much do you predict that they will donate.
  - Thus  $f_2(Y \mid X = 0) = 0$  since people that do not donate give a total donation of zero.
- Subtract cost of mailing from predicted donations. We can do this because we inherently assume that people we do not mail to do not donate.

Predicted Profits = 
$$\sum_{x \in X, y \in Y} f(x, y) = f(y \mid x) f(x) - z$$

## Methods

## **Feature Engineering**

- Problem: The dataset is not clean many values are missing, and most variables are nonbinary, posing as difficulties in running predictive models.
- **Solution:** Cleaned data using helper functions, and dropped some variables out of >500 original variables

#### **REMOVED**

## 70 variables

Usual justification

- Insufficient data: over 50% missing
- Inconsistent data
- Redundant data

#### **IMPUTE TO MEAN**

## 68 variables

Impute missing values to mean of dataset.

#### **IMPUTE TO 0**

## 16 variables

Impute missing values to zero.

#### **AS INDICATOR**

## 4 variables

- Variable only has entries in a fraction of the data
- more important that the variable exists rather than the value

#### **Data Splits:**

#### Given

KDD provided 50% training data and 50% testing data.

#### Modification

- Split KDD training data into 80-20 training:val
- Final: Train 40% Validation 10% Test 50%

## "Quick Stepwise" Procedure Outline

#### Main Problems - Exact methods

- Running this dataset (90000 x 500) using CPU would take a long time for random forest using R. Logistic regressions do not converge.
- Cumbersome to run stepwise methods for both logistic and linear regressions for all predictors

Need a <u>reasonable approximation</u> to the stepwise procedure in order to remove unnecessary predictors in our model.

#### Pseudocode for "Quick Stepwise"

---

numtrials = 5

oldmodel = regression on full model (without intercepts)

for trial in range(numtrials){

predictorset Remove predictors that have p-

values < 0.08

**newmodel =** regression using predictors on

predictorset (without intercept)

oldmodel = newmodel

return **newmodel** }

#### Why Quick Stepwise works

---

- Many useless predictors are non-significant
- To be have p-values less than 0.08, 5 times in separate regression requires to predictor to be very significant.
- Reducing the p-value threshold below 0.08 or increasing number above 5 makes it too conservative dropping certain significant predictors that improve our model.
- Since our goal is prediction, we don't mind having a few substandard predictors with a model with mostly significant predictors.

## Implementation

## **Predicting Responses**

## **Logistic Regression Implementation**

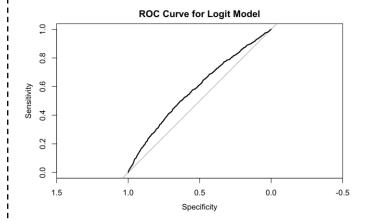

#### **Final Model Coefficients**

After implementing "Quick Stepwise" we got a result of 31 predictors that incorporated data from the following:

- % of Homeowners
- Number of children
- Income
- Statistics on methods of transportation
- Median years of school completed by adults age 25+,
- % Veterans serving in last 23 years.
- % Houses with telephones
- Number of card promotions received in last 12 months
- · Past promotion giving history

### $AUC_ROC = 0.585$

## Predicting Responses Logistic Regression Results

- We calculated the predicted logit values on the validation dataset and organized them by decile.
- We organized the logit values by decile and captured the amount of donors captured in our validation dataset.
- The % Donors captured generally decreases as we lower our threshold.
   This indicates stability in our model.

Conversions by decile	% Donors Captured in Validation Set
Top 10%	17.33%
Top 20%	12.62%
Top 30%	12.00%
Top 40%	10.36%
Top 50%	8.51%
Top 60%	9.23%
Top 70%	8.51%
Top 80%	7.49%
Top 90%	6.97%
All of the data	6.97%

## **Predicting Donations**

## **Linear Regression**

#### **Final Model Coefficients**

After implementing "Quick Stepwise" for our linear model we got **15** predictors that incorporated data from the following:

- Statistics on method of transportation
- Percent employed in educational services
- Communities with white people of age < 15</li>
- Past giving history
- Percent adults age 60-64

#### **Optimal Linear Regression Fit**

#### **Precautions taken**

- Removed predictors that were highly correlated and had high collinearity (if there was any)
- Limited correlation between residuals and predictors (checking residual plots)
- Removed outlier points. By checking studentized residuals.

$$R^2 = 0.8166$$

Adjusted  $R^2 = 0.8159$ 

#### **Key Insight**

Note that in both regression models, there is a heavy reliance on <u>past</u> giving history.

## **Profit Methodology**

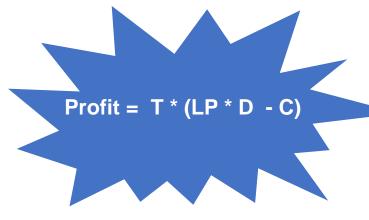

#### **Logit Thresholds for Targeting**

- These logit probabilities indicate the probability that a given person will donate
- Our targeting scheme will target consumers who have a greater probability of buying above a certain threshold probability
- People in the top 10% are over twice as likely to buy than people in the bottom 10%!

#### **Profit Formula Used**

Variable	Description
LP	Logit Probabilities
D	Predicted Donations
Т	Targeting indicator (if LP > threshold then 1 else 0)
С	Cost of mailing promotion

Deciles	Logit Thresholds
Top 10%	0.072
Top 20%	0.064
Top 30%	0.058
Top 40%	0.054
Top 50%	0.049
Top 60%	0.045
Top 70%	0.041
Top 80%	0.036
Top 90%	0.030
All of the data	0

### **Profit Results on Validation Set**

#### **Profit Predictions on Validation Set**

Logit Score Thresholds	Incremental Profits by Decile	Profits Including Decile and Up
Top 10%	\$649.30	\$649.30
Top 20%	\$478.17	\$1127.26
Top 30%	\$360.06	\$1487.20
Top 40%	\$365.79	\$1852.96
Top 50%	\$336.84	\$2189.65
Top 60%	\$298.00	\$2487,77
Top 70%	\$170.86	\$2658.28
Top 80%	\$90.89	\$2749.35
Top 90%	- \$8.55	\$2740.78
All of the data	- \$308.19	\$2365.94

#### **Validation Results**

- Our model answers the question by evaluating people who are NOT our donors, by taking the top 80% of logit scores
- Through this approach we get excellent results in our validation set
- This exercise has helped us choose our threshold for the testing dataset

Actual Profits	\$2664.74
Predicted Profits	\$2749.35

## **Profit Results on Testing Set**

While we underestimated the baseline profits, our net profits were very accurate.
 This is very encouraging because we replicated the same results form our validation set.

	KDD Testing Set* Actual Results (provided by organization)	Our Predicted Results
Net Profits	\$14,712	\$14,468
Baseline Profits if entire population is targeted	\$10,560	\$12,329
Increase in Net Donation	\$4,152	\$2,139
% Increase	39.32%	\$17.35%

Achieved similar results as organizing committee despite utilizing much simpler models than winners

# Monitoring & Adaptation

Since we did not work directly with the client, these are recommendations only

## **Monitoring**

#### **Model Evaluation**

#### Evaluate the model yearly

- As new mailings are sent out every year
- Crucial, as giving history (RAMNT\_??) variables tend to be predictive of future giving behaviour
- New donors can be sourced and added to the dataset with every mailing

#### Possible Adjustments

- Probability thresholds from logistic regression for deciles
- Ensure that all deciles that yield donations are profitable.

#### **Tracking Model Performance**

#### Key indicators

- AUC\_ROC: measuring logistic regression model fit
- Capture rate by decile. The more skewed it is towards higher deciles, the better the model.
- Adjusted R^2 Of those who gave, were the amounts comparable with predictions?
- Linear regression assumptions. If it does not, we have to incorporate a different machine learning framework. Linear models are powerful only if they obey the assumptions.

## **Adaptation**

#### **New Data Elements**

#### **New Mailing Types**

- Rise of digital / non-print advertising campaigns in philanthropy
- "Premiums" sent with the mailing campaigns may change
- Response variables remain unchanged

#### New Data Variables

- Online footprint variables
- Old interest variables no longer predictive

#### Incorporating / Selecting New Predictors

- Model automatically does this whenever rerun through the step-wise procedure
- Provided data is coded correctly

#### **New Campaign Types**

#### May need to consider a new baseline if

- Donors are able to give passively without need for targeted campaigns
- Why? Because the "blanket policy" baseline will now overestimate profits from targeting

#### How to calculate a new baseline

- Run a randomized experiment to create a control group
- Duration: a year, or the usual time window for responses to a campaign
- Establish baseline donation amount that does not require cost of targeting and promotion

## **Limitations**

#### **Dataset**

#### Many variables either had dirty or insufficient data

- Data was not consistently coded, and we did not have a way of inferring what certain entries meant
- Many variables had over >50% blanks, could not possibly impute the rest
- Some of these variables may have been predictive if coded accurately
  - Gender
  - Wealth
- Some indicator variables are predictive but not defensible
  - E.g. CLUSTER each cluster has unique socioeconomic, interest and demographic characteristics. Some cluster numbers were predictive, but the assignment of clusters was not known to us

#### Model

#### Limited cost information affecting profitability calculus

- PVA has different types of mailings, and they presumably have an effect on responses as well as cost
- Differentiated cost information was not given, and we were forced to treat all mailing types as the same

#### May cause donor pool shrinkage

- The catch: All who are not targeted in the upcoming campaign will definitely not donate.
- Feedback loop: if you don't donate this time (whether not targeted, or no response), model unlikely to target you again
- Mitigation: must constantly add new donors from new sources

. \*

## **Alternative Approaches**

#### Classification

## We could have tried multiple methods and pick the one with the best accuracy:

- Random Forest / Ensemble Methods / Decision Tree
- Support Vector Machines

#### Clustering

 K-means to discover heterogenous relationships. Since there was limited heterogeneity, we could have done Kmeans and trained separate regression models for each cluster, giving us a more nuanced result.

#### Regression

- Forward Stepwise Method in choosing predictors.
- Selective Inference (to choose predictors judiciously). Using this framework, we can use the same predictors across multiple mailings because of the strength of significance.
- Regression Trees (in case linear model assumptions do not hold.)
  - In our model we faced a mild heteroskedasticity problem. In other mailings we cannot guarantee the validity of the linear model. Regression trees can help us get out of this problem.

### **The Bottom Line**

- Modelled philanthropy as a joint distribution of 2 utility functions
  - Give / Not Give
  - How Much
- 2. Gain by saving on cost:

  by not mailing those who would not have given (omitting bottom 20%)

\$14,468

Raw Profit

\$2,139

Above Baseline
